*Presenting author

BACKGROUND

- Previous studies have shown that male gender is an independent predictor of organ damage in patients with systemic lupus erythematosus (SLE), particularly in the early stages of their disease^{1,2}
- In the previous GLADEL cohort, male patients were found to have a higher SDI (SLICC/ACR Index) than their female counterparts, although this difference was not statistically significant³

OBJECTIVE

This study aimed to evaluate the impact of gender on organ damage (as assessed by SDI) in patients with SLE in the GLADEL 2.0 cohort

METHODS

STUDY POPULATION

- GLADEL 2.0 is an observational, multiethnic, multinational Latin American SLE cohort
- A total of 44 centers from 10 Latin American countries enrolled patients ≥18 years of age who met the 1982/1997 American College of Rheumatology (ACR) and/or the 2012 Systemic Lupus International Collaborating Clinics (SLICC) classification criteria

STATISTICAL ANALYSIS

- Continuous variables were summarized as medians (interquartile ranges) and categorical variables as frequencies (percentages)
- Logistic regression modeling was used to identify factors associated with the increase in the SDI between the baseline visit and the end of follow-up
 - P values <0.05 were considered statistically significant
- An interaction analysis between gender and time was performed using a mixed R model, with SDI as a dependent variable and gender (between-subjects) and time (within-subjects) as independent variables
 - A random intercept per participant was included to control for within-subject variability
- All analyses were descriptive and were done using R v4.40

RESULTS

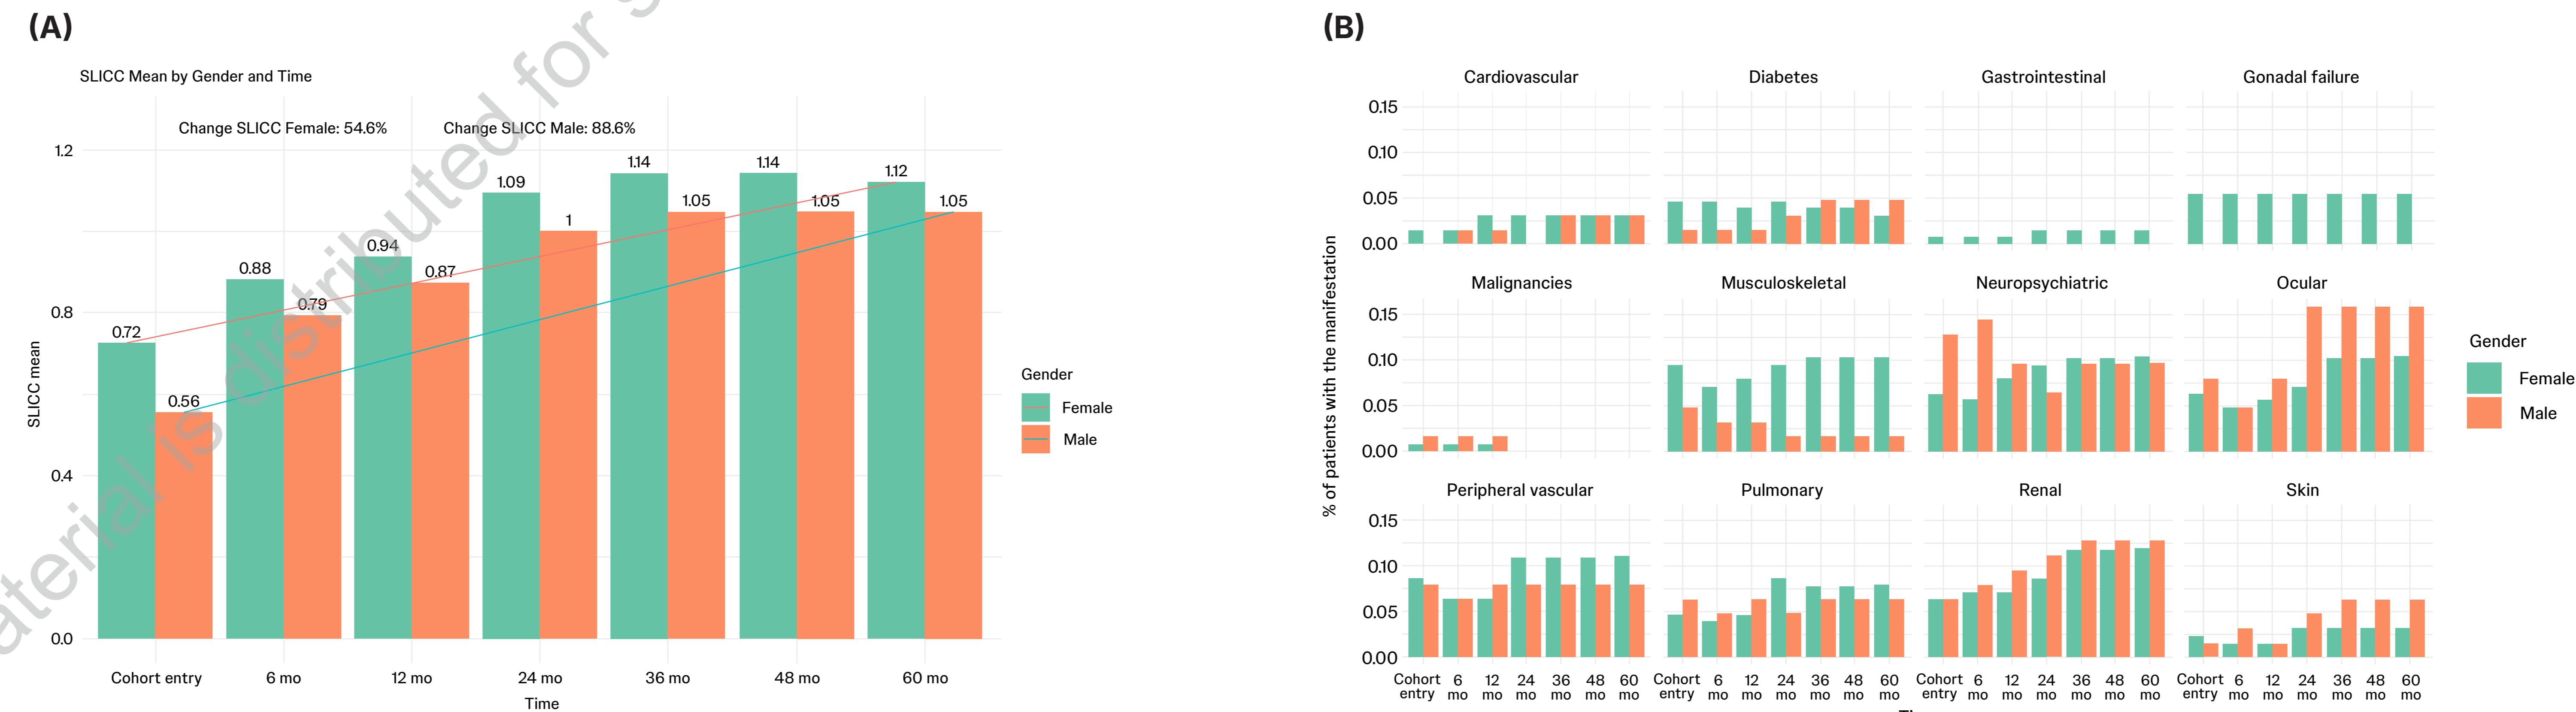

- Of the 1081 patients enrolled in the GLADEL 2.0 cohort, 385 patients matched by gender were considered (**Table 1**)
 - 190 patients completed at least four annual visits and were included in these analyses
 - 70% of the patients were women and 30% were men
- No statistically significant differences in organ damage as measured by the SDI were found between male and female patients ($P=0.563$)
 - This trend remained constant throughout the follow-up period, with no significant interactions observed ($P=0.904$)
- However, the percentage of patients who had an increase in the SDI at the end of the follow-up period was higher among male versus female patients (88.6% vs 54.6%; **Figure 1A**)
 - The accrual of damage over the follow-up time increased significantly for both male and female patients
- The frequency of affected SDI domain was examined both at baseline and during follow-up (**Figure 1B**)
 - In general, males had a higher occurrence of ocular, cutaneous, and malignant involvement compared with females
 - Females had a higher frequency of gastrointestinal, pulmonary, peripheral vascular, and musculoskeletal involvement than males
- After adjusting for sociodemographic and clinical/immunologic characteristics, multivariate analysis found that disease duration (OR: 1.05; 95%CI: 1.0–1.1) and disease activity, as measured by the SLEDAI-2K (OR: 1.05; 95%CI: 1.0–1.1), were associated with a higher likelihood of an increase in SDI

TABLE 1:
Sociodemographic and clinical characteristics of patients with SLE by gender

	Male (n=113)	Female (n=272)	P value	Total (N=385)
<i>Age at diagnosis, years, median (IQR)</i>	27.6 [22.6–37.6]	26.2 [20.0–35.1]	0.129 0.204	26.5 [20.9–35.5]
<i>Ethnic group, n (%)</i>				
Afro-Latin American	6 (5.4)	26 (9.6)		32 (8.4)
Indigenous	2 (1.8)	1 (0.4)		3 (0.8)
Mestizo	82 (73.2)	178 (65.7)		260 (67.9)
White	22 (19.6)	65 (24.0)		87 (22.7)
Other	0 (0)	1 (0.4)		1 (0.3)
<i>Socioeconomic status, n (%)</i>			0.287	
High	3 (2.7)	6 (2.3)		9 (2.4)
Upper middle	21 (18.9)	40 (15.3)		61 (16.4)
Middle	49 (44.1)	94 (35.9)		143 (38.3)
Lower middle	28 (25.2)	94 (35.9)		122 (32.7)
Low	10 (9.0)	28 (10.7)		38 (10.2)
Missing	2 (1.8)	10 (3.7)		12 (3.1)
<i>Medical coverage, n (%)</i>			0.154	
Total coverage	62 (55.9)	142 (53.0)		204 (53.8)
Partial coverage	20 (18.0)	33 (12.3)		53 (14.0)
Without coverage	29 (26.1)	93 (34.7)		122 (32.2)
Missing	2 (1.8)	4 (1.5)		6 (1.6)
<i>SLICC at baseline, median (IQR)</i>	0 [0–1.00]	0 [0–1.00]	0.56	0 [0–1.00]
<i>Disease duration, years, median (IQR)</i>	2.35 [0.192–8.92]	2.91 [0.562–9.82]	0.286	2.70 [0.452–9.50]
<i>Use of glucocorticoids at baseline, n (%)</i>	64 (97.0)	158 (59.8)	1.000	222 (96.1)
<i>Use of antimalarial at baseline, n (%)</i>	64 (97.0)	162 (97.0)	1.000	226 (97.0)
<i>Type of lupus, n (%)</i>			0.838	
1=Patient with SLE, no history of lupus nephritis	31 (27.4)	82 (30.1)		113 (29.4)
2=Patient with SLE, with prevalent inactive lupus nephritis	21 (18.6)	55 (20.2)		76 (19.7)
3=Patient with SLE, with active prevalent lupus nephritis	28 (24.8)	67 (24.6)		95 (24.7)
4=Patient with SLE, with incident (active) lupus nephritis	33 (29.2)	68 (25.0)		101 (26.2)

PRESENTED AT: EUROPEAN ALLIANCE OF ASSOCIATIONS FOR RHEUMATOLOGY (EULAR) JUNE 11-14, 2025; BARCELONA, SPAIN.

CONCLUSIONS

- Although male gender was not associated with an increased risk of damage accrual, the proportion of patients whose SDI increased was higher in males than females
- Organ damage during follow-up was significantly increased in both genders
- As patients are followed closely for a longer duration, the impact of gender on damage accrual may become more apparent
